3

Conclusion

## Definition of Gestational Diabetes Mellitus

- Carbohydrate intolerance  
of variable severity  
with onset or first recognition  
during the present pregnancy.

\* "Gestational" diabetes implies that this disorder is induced by pregnancy, perhaps due to exaggerated physiological changes in glucose metabolism

Third International Workshop-Conference on GDM, 1991  
ACOG Practice Bulletin, 2001

## Limitation of GDM Definition

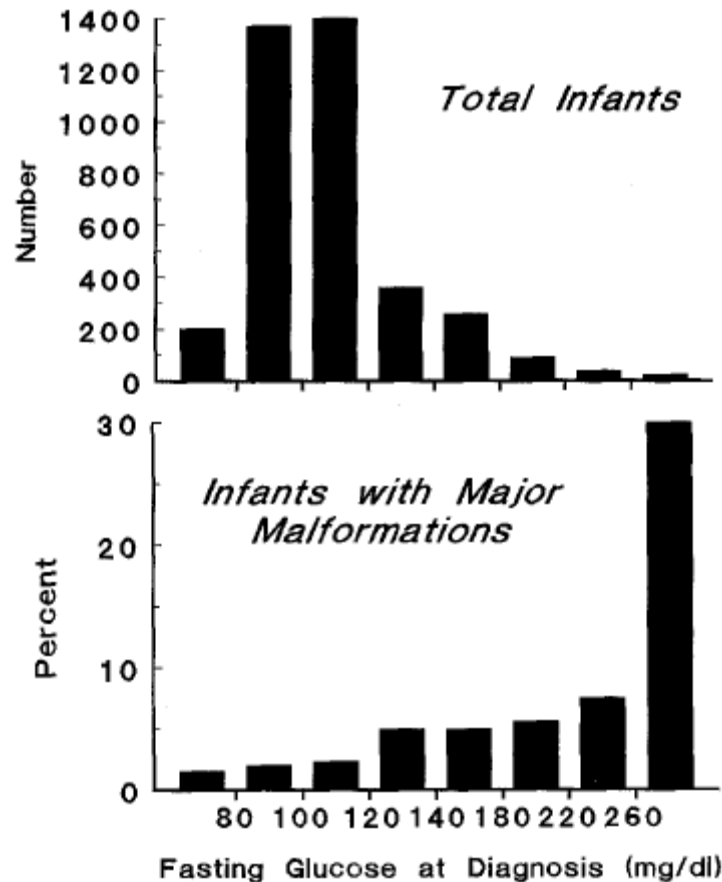

- Definition does not exclude the possibility that unrecognized glucose intolerance may have antedated or begun concomitantly with the pregnancy (Pregestational diabetes/ Overt DM )

Glucose level before dinner (mg/dL, mean ± SD)	82.1 ± 17.3	77.1 ± 14.6	<i>P</i> = .039
Glucose level after dinner (mg/dL, mean ± SD)	102.8 ± 26.0	93.7 ± 17.3	<i>P</i> = .01
Mean glycemic profile (mg/dL, mean ± SD)	96.7 ± 15.0	87.6 ± 10.4	<i>P</i> = .00002
Glycosylated hemoglobin (% , median and interquartile range)	4.5 (4.2-5.2)	4.6 (4.3-4.9)	NS
Insulin therapy (No.)	22/65 (33.9%)	12/170 (7.1%)	<i>P</i> < .00001

NS, Not significant.

**Table IV.** Obstetric and neonatal outcomes

	<i>Early-onset gestational diabetes (n = 50)</i>	<i>Late-onset gestational diabetes (n = 133)</i>	<i>Statistical significance</i>
Vaginal births	38 (76%)	107 (80.5%)	NS
Cesarean deliveries for fetal distress	1 (8.3%)	2 (7.7%)	NS
Cesarean deliveries for fetopelvic disproportion	4 (33.3%)	12 (46.2%)	NS
Cesarean deliveries for failed induction	1 (8.3%)	1 (3.9%)	NS
Gestational age at birth (wk, mean $\pm$ SD)	39.0 $\pm$ 2.7	39.3 $\pm$ 1.7	NS
Preterm births	3 (6%)	7 (5.3%)	NS
5-min Apgar score <7	1 (2%)	4 (3.0%)	NS
1-min Apgar score <6	6 (12%)	6 (4.5%)	NS
Neonatal weight (g, mean $\pm$ SD)	3419.6 $\pm$ 643.3	3281.4 $\pm$ 580.9	NS
Small for gestational age	5 (10%)	20 (15.0%)	NS
Macrosomia (>4000 g)	7 (14%)	11 (8.3%)	NS
Meconium passage	9 (23.1%)	24 (21.8%)	NS
Special care baby unit admission	5 (10%)	14 (10.5%)	NS
Neonatal hypoglycemia	4 (8%)	0 (0%)	<i>P</i> = .005
Low birth weight (<2500 g)	0 (0%)	6 (4.5%)	NS
Perinatal deaths	3 (6%)	0 (0%)	<i>P</i> = .02

*NS*, Not significant.

## Proposal for the Reconsideration of the Definition of Gestational Diabetes

In 1997, the American Diabetes Association (ADA) announced a new diagnostic criterion for diabetes and set the definition of gestational diabetes mellitus (GDM). Before 1991, GDM was defined as “a transient abnormality of glucose tolerance during pregnancy” (2–4). However, the 1997 definition of GDM by the ADA includes diabetes diagnosed during pregnancy. This definition ignores the added risks to the mother and to the fetus when the mother has undiagnosed type 2 diabetes. We propose reconsideration of the definition, which would separate diabetes and slight abnormal carbohydrate, so-called GDM, to provide a better model of care for type 2 diabetic pregnant women.

There are three problems concerning an undiagnosed type 2 diabetic woman that are not major issues in pregnant women who are first diagnosed with abnormal glucose tolerance in pregnancy

In this cohort, the congenital malformation rate from GDM patients was 1.9% and was no different from the rate in the general Japanese population. In contrast, the congenital malformation rate in infants of type 2 diabetic mothers diagnosed during pregnancy was higher than that of children from pregestational diabetic mothers treated during pregnancy, 12.7 vs. 4%, respectively.

There were no GDM patients with retinopathy. However, the rate of background retinopathy was 12.7% and proliferative retinopathy was 4.2% in the type 2 diabetic women diagnosed for the first time during pregnancy.

Similar rates and complications were seen in a cohort of pregnant women in Santa Barbara, California, where a total of 49,861 pregnancies occurred in our Mexican-American population from 1997 to 2004. A total of 4,133 (8.3%) had a positive OGTT based on the ADA criteria (1). However, 40% of the GDM women had type 2 diabetes first diagnosed during pregnancy based on our criteria: acanthosis nigrans, requiring insulin before the 12th week of gestation, because they failed to maintain goals with dietary intervention alone (6). Five percent of the type 2 women had retinopathy, and 7% had significant proteinuria at time of diagnosis.

## Hyperglycemia and Adverse Pregnancy Outcomes

The HAPO Study Cooperative Research Group\*

The Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study reported in this issue of the Journal is an elegantly designed, very large, international study that answers previous questions by clearly demonstrating that **there is a continuum of risk, without clear thresholds, between carbohydrate intolerance in pregnancy and adverse pregnancy outcomes.** The HAPO study investigators assessed the pregnancy outcomes of more than 23,000 women with glucose values of less than 200 mg per deciliter 2 hours after a 75-g glucose load.

## Glucose categories

	FPG	1hr plasma glc	2hr plasma glc
<b>1</b>	~75	~105	~90
<b>2</b>	75~79	106~132	91~108
<b>3</b>	80~84	133~155	109~125
<b>4</b>	85~89	156~171	126~139
<b>5</b>	90~94	172~193	140~157

**Table 3. Adjusted Odds Ratios for Associations between Maternal Glycemia as a Continuous Variable and Primary and Secondary Perinatal Outcomes.\***

Outcome	Plasma Glucose Level		
	Fasting	At 1 Hr	At 2 Hr
	<i>odds ratio (95% CI)</i>		
<b>Primary outcome</b>			
Birth weight >90th percentile	1.38 (1.32–1.44)	1.46 (1.39–1.53)	1.38 (1.32–1.44)
Primary cesarean section†	1.11 (1.06–1.15)	1.10 (1.06–1.15)	1.08 (1.03–1.12)
Clinical neonatal hypoglycemia	1.08 (0.98–1.19)‡	1.13 (1.03–1.26)	1.10 (1.00–1.12)
Cord-blood serum C peptide >90th percentile	1.55 (1.47–1.64)	1.46 (1.38–1.54)	1.37 (1.30–1.44)
<b>Secondary outcome</b>			
Premature delivery (before 37 wk)	1.05 (0.99–1.11)	1.18 (1.12–1.25)	1.16 (1.10–1.23)
Shoulder dystocia or birth injury	1.18 (1.04–1.33)	1.23 (1.09–1.38)	1.22 (1.09–1.37)
Intensive neonatal care	0.99 (0.94–1.05)	1.07 (1.02–1.13)	1.09 (1.03–1.14)
Hyperbilirubinemia	1.00 (0.95–1.05)	1.11 (1.05–1.17)	1.08 (1.02–1.13)
Preeclampsia	1.21 (1.13–1.29)	1.28 (1.20–1.37)	1.28 (1.20–1.37)

\* Odds ratios were for an increase in the glucose level of 1 SD (6.9 mg per deciliter [0.4 mmol per liter] for the fasting plasma glucose level, 30.9 mg per deciliter [1.7 mmol per liter] for the 1-hr plasma glucose level, and 23.5 mg per deciliter [1.3 mmol per liter] for the 2-hr plasma glucose level). The model for preeclampsia did not include adjustment for hospitalization or mean arterial pressure, and presence or absence of family history of hypertension or prenatal urinary tract infection was included in the model for preeclampsia only. See Table 2 for other details about adjustments in each model.

† Data for women who had had a previous cesarean section were excluded.

‡ The P value for the quadratic (nonlinear) association was 0.013.

# Considerations (1)

- \*\* Fasting plasma glucose
  - impractical at first prenatal visit in many settings
  - Additional visit for test of FBS ???

# Considerations (2)

plasma glucose : 1140 won

HbA1C: 6840 won

# Conclusions

- In Korean women with 25-39 years old,
  1. Prevalence of diabetes may be 0.6-2.5%.
  2. Prevalence of metabolic syndrome may be 4-11 %
  3. Metabolic test is performed in only 16-25% in this age group.

Thank you for your attention

## **Screening and Diagnosis of Gestational Diabetes Mellitus**

**ABSTRACT:** *Gestational diabetes mellitus (GDM), defined as carbohydrate intolerance that begins or is first recognized during pregnancy, is associated with increased maternal, fetal, and neonatal risks. The prevalence of GDM in the United States is increasing, probably because of increasing rates of overweight and obesity. A universal recommendation for the ideal approach for screening and diagnosis of GDM remains elusive. At this time, the Committee on Obstetric Practice continues to recommend a two-step approach to screening and diagnosis. All pregnant women should be screened for GDM, whether by patient history, clinical risk factors, or a 50-g, 1-hour glucose challenge test at 24–28 weeks of gestation. The diagnosis of GDM can be made based on the result of the 100-g, 3-hour oral glucose tolerance test, for which there is evidence that treatment improves outcome.*

## Problems of old criteria

- None of the currently recommended Dx criteria are based on pregnancy outcome
- The differing glucose challengers and Dx criteria
  - Exceedingly difficult in comparison of prevalence and pregnancy outcomes across the world

## Hyperglycemia and Adverse Pregnancy Outcomes

The HAPO Study Cooperative Research Group\*

The Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study reported in this issue of the Journal is an **elegantly designed, very large, international study** that answers previous questions by clearly demonstrating that there is a continuum of risk, without clear thresholds, between carbohydrate intolerance in pregnancy and adverse pregnancy outcomes. The HAPO study investigators assessed the pregnancy outcomes of more than 23,000 women with glucose values of less than 200 mg per deciliter 2 hours after a 75-g glucose load.

# HAPO study

# Primary and Secondary Outcomes

## Primary outcomes

1. birth weight above the 90th percentile for gestational age
2. primary cesarean delivery
3. clinical neonatal hypoglycemia,
4. cord-blood serum C-peptide level above the 90th percentile (fetal hyperinsulinemia) or 1.7 microg/Liter

## Secondary outcomes

1. premature delivery (before 37 weeks of gestation)
2. shoulder dystocia or birth injury
3. need for intensive neonatal care
4. hyperbilirubinemia,
5. preeclampsia

## Glucose categories

	FPG	1hr plasma glc	2hr plasma glc

## The Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study: paving the way for new diagnostic criteria for gestational diabetes mellitus

Donald R. Coustan, MD; Lynn P. Lowe, PhD; Boyd E. Metzger, MD; Alan R. Dyer, PhD

The Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study was performed in response to the need for internationally agreed upon diagnostic criteria for gestational diabetes, based upon their predictive value for adverse pregnancy outcome. Increases in each of the 3 values on the 75-g, 2-hour oral glucose tolerance test are associated with graded increases in the likelihood of pregnancy outcomes such as large for gestational age, cesarean section, fetal insulin levels, and neonatal fat content. Based upon an iterative process of decision making, a task force of the International Association of Diabetes and Pregnancy Study Groups recommends that the diagnosis of gestational diabetes be made when any of the following 3 75-g, 2-hour oral glucose tolerance test thresholds are met or exceeded: fasting 92 mg/dL, 1-hour 180 mg/dL, or 2 hours 153 mg/dL. Various authoritative bodies around the world are expected to deliberate the adoption of these criteria.

TABLE 5

**Comparison of proposed thresholds to current thresholds for 75 gram OGTT in pregnancy (ADA)**

Sample time	Proposed glucose threshold, mg/dL	Current ADA recommendations
Fasting	92	95
1-h	180	180
2-h	153	155

Proposed: gestational diabetes is diagnosed if  $\geq 1$  of the thresholds is met or exceeded.<sup>16</sup> Current ADA recommendations: gestational diabetes is diagnosed if  $\geq 2$  thresholds are met or exceeded.<sup>12</sup>  
 ADA, American Diabetes Association, OGTT, oral glucose tolerance test.

The editors of the Journal and the SMFM Publication Committee are pleased to provide this summary of a debate conducted at the 31st annual meeting of the Society for Maternal–Fetal Medicine (The Pregnancy Meeting), San Francisco, CA, Feb. 7-12, 2011. One entry in this series will run every month from May through October 2011.

## Gestational diabetes—Staying with old or marrying new guidelines

**THE ISSUE:** Gestational diabetes mellitus is associated with increased neonatal morbidities and higher cesarean delivery rates; women with gestational diabetes mellitus are at increased risk for type II diabetes mellitus later in life. The current recommendation for screening includes a glucose tolerance test either early in pregnancy and/or at 24-28 weeks' gestation followed by a diagnostic 100-g oral 3-hour glucose tolerance test with a rate of 5%. The results of a large prospective observational study (HAPO study) and 2 randomized trials lead the International Association of Diabetes in Pregnancy Study Group to recommend a 1-stage screening and diagnosis method that includes a 75-g 2-hour glucose tolerance test that will result in an 18% gestational diabetes mellitus rate. However, there is uncertainty about the clinical implications of the adoption of the latter recommendation.
